To explain the efficiency of CF neutrophils in resisting rhinovirus infection, a simple mathematical model of neutrophil antiviral activity is described. The model accurately predicts the persistence of infection in CF and non-CF subjects, the increase in neutrophils from CF and normal subjects in response to infection, and the accelerated clearance of virus from CF subjects. Neutrophil functions are inversely correlated with activation state: cell function is reduced in hypo-reactive neutrophils from CF and controls, normal in hyper-reactive neutrophils from CF, and increased in normal neutrophils from CF patients. In CF neutrophils, infection induces a more-pronounced increase in number of cells which are hyper-reactive and which have a more-pronounced and less-pronounced decrease in function. Simulations show that these two features account for the persistence of infection in CF and normal subjects and increased virus clearance from CF subjects, respectively. The CF neutrophil phenotype may be the result of a negative selection process which causes neutrophils from CF subjects to evolve. Renal oncocytoma Renal oncocytoma, also known as renal oncocytosis, is a tumour that occurs in the renal pelvis, which is a common site for benign tumours. It can be classified into two types: Oncocytoma with papillary architecture arising in the renal pelvis (so-called papillary oncocytoma). Oncocytoma without papillary architecture, arising in the renal cortex (so-called clear cell oncocytoma). Oncocytomas with papillary architecture can be divided into three subtypes: Intratubular oncocytoma (ITO). These are small (7.5-12.5 mm) oncocytomas with papillary architecture that develop in the renal tubular lumen. Oncocytomas with papillary 1678e9f9e
